ABSTRACT

This report contains data on the annual earnings of husbands and wives and their combined earnings as married couples. A narrative summarizing findings precedes each group of related charts and tables. Figures 1A through 1C and tables 1A through 1D classify the earnings of married couples, husbands, and wives by weeks of work and full-time/part-time status for 1981. Figures 2A and 2B and tables 2A through 2D provide data on the earnings of married couples, husbands, and wives by occupation of longest job in 1981. Figures 3A through 3C and tables 3A through 3D contain earnings data for married couples, husbands, and wives by their educational attainment level. Figure 4 and tables 4A through 5B use the age of the husband and wife and presence of own children as major classifiers. The data in figure 5 and table 6 show wives with earnings greater than their husbands. The final figure and final four tables, 7A through 8B, present mean earnings figures for husbands and wives working year round, full time. Mean earnings are shown by age, occupation, and educational attainment. Appendixes include definitions and information on source and reliability of the estimates. (YLB)

Earnings in 1981 of Married-Couple Families, by Selected Characteristics of Husbands and Wives

INTRODUCTION

This report contains data on the annual earnings of husbands and wives and their combined earnings as married couples for 1981. Earnings data are presented using three important determinants of earnings levels: (1) annual work experience in terms of weeks worked and full-time or part-time employment, (2) occupation, and (3) level of educational attainment. Earnings levels of husbands and wives by age and presence of children are presented and discussed, and a table has also been included showing the number and characteristics of wives having higher earnings levels than their husbands. The data in the report were obtained from the March 1982 Current Population Survey (CPS).

The main purpose of this report is to provide specialized data on the earnings of husbands and wives that have not been available in the annual Current Population Reports, Consumer Income Series (P-60). The steep rise in labor force participation of women make this report's statistics increasingly important to understanding the distribution of earnings and income. The 20-year period between 1961 and 1981 saw the annual average number of women in the labor force increase from 23.8 to 46.9 million, compared with an increase for men from 49.2 to 63.9 million. About 67 percent of all married couples with earnings had a working wife. Overall, working wives contributed about 30 percent of the couples' earnings when both the husband and wife worked and 38 percent in situations where both worked year round, full time. Comparisons such as this and many others can be made based on the data in this report.

It should be noted that the data in this report cover 1981, a year in which the U.S. economy fell into a recession that lasted from July 1981 to November 1982. This situation may have had some effect on the relationship between the earnings of husbands and wives. Differences between the earnings of husbands and wives result from a multitude of factors, and because we have covered only some of the major determinants of earnings in this report, comparisons of husbands and wives earnings levels cannot be used to examine issues such as sex discrimination and differences in the monetary gains from education. Also, husbands and wives are only a subset of all workers. These kinds of analyses should be based on more detailed statistics from persons with similar educational backgrounds, degrees, specific occupations, and previous lifetime work experience.

HIGHLIGHTS

- Both the husband and wife had earnings in 62 percent of the 42.2 million married couples with at least one spouse employed during 1981.
- The average earnings of married couples was $25,550, overall, but $34,560 if both husband and wife worked year round, full time.
- Forty-six percent of the 27.7 million working wives worked year round, full time in 1981. These women earned an average of $13,070 in 1981.
- Seventy-six percent of the 40.2 million husbands with earnings were year-round, full-time workers. Their earnings averaged $23,800.
- The average earnings of married couples in which both the husband and wife were employed in professional or managerial occupations in 1981 was $39,170.
- About 17 percent of working wives in 1981 had 4 or more years of college. Those wives with a 4-year degree earned an average of $10,680.
- Wives with 5 or more years of college averaged $14,910.
- Twenty-four percent of husbands working in 1981 had 4 or more years of college. Those with 4 years of college earned an average of $27,340, and those with 5 or more years of college earned an average of $32,860.
- Women with at least one minor child in the home accounted for 55 percent of all wives with earnings.
- Sixteen percent of the 25.7 million married couples with both spouses employed had a wife whose earnings exceeded her husband's in 1981.

Work Experience in 1981

Tables 1A through 1D classify the earnings of married couples, husbands, and wives, by weeks of work and full-time, part-time status for 1981. In March 1982, there were 49.6 million married couples. Of these, about 42.2 million (85 percent) had a husband, or wife, or both working in 1981. Eighty-nine percent had a husband working at full-time jobs, and 44 percent had a wife with the same work experience status. About 26.3 million (62 percent) had both the husband and wife working. The survey showed that 95 percent of the husbands were earners in married-couple families with earnings. In contrast, 67 percent of the wives were earners in 1981. The remaining 33 percent of wives in these families did not work outside the home. Both the husband and the wife were employed year round, full time in 23 percent of the total number of married-couple families with earnings in 1981.

The mean earnings of married-couple families with earnings was $25,550 in 1981. When both the husband and wife worked, the mean earnings was $28,560, but $34,560 if both worked year round, full time. For the 14.0 million families in which the husband worked but the wife did not, the mean earnings was $22,300.

Overall, 40.2 million husbands were earners in 1981. The mean earnings of these men was $20,870. Those working year round, full time earned an average of $23,800. Husbands working year round, full time whose wife did not work earned somewhat more, $26,170, on average.

Working wives with earnings numbered 27.7 million in 1981. The mean earnings of these women was $8,600 in 1981. Wives working year round, full time, about 46 percent of the total, earned an average of $13,070. About one-third of these wives with earnings were employed part time in 1981; these women earned an average of $3,830.

Overall, working wives earned an average of about 43 percent of the amounts earned by their husbands. The same comparison for husbands and wives both working year round, full time shows that wives earned about 62 percent of the amounts received by husbands.

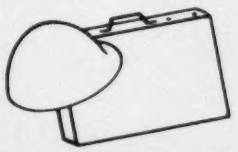
Occupation of Longest Job in 1981



Tables 2A through 2D provide data on the earnings of married couples, husbands, and wives by occupation of longest job in 1981. The data show that the most frequent combination of occupations for husbands and wives was a husband in the crafts occupations and a wife in the clerical occupations in 1981. There were 2.1 million of these couples in 1981, about 8 percent of all married couples with both the husband and wife employed. The mean earnings of this group was $27,800. The mean earnings for couples with both the husband and wife in either a professional or managerial occupation was $39,170.

Approximately 23 percent of employed husbands were in the crafts occupations in 1981; these men earned an average of $18,720 in that year. Husbands in the professional and managerial occupations had the highest earnings levels, while farm workers had the lowest earnings.

The largest proportion of working wives were concentrated in the clerical occupations: 34 percent were working in this occupation group in 1981, earning an average of $8,900. Wives in the professional and managerial occupations numbered 7.1 million, or 26 percent of the 27.7 million working wives. The mean earnings of this group was $12,200 for 1981.

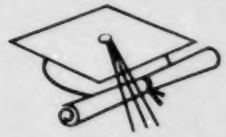
Years of School Completed



Tables 3A through 3D contain earnings data for married couples, husbands, and wives by their educational attainment levels. One in four married couples were made up of two high school graduates, compared with a figure of 11 percent for married couples in which both the husband and wife completed 4 or more years of college. Those couples in which neither spouse completed high school numbered 5.5 million, or about 13 percent of married couples with earnings.

The mean earnings of couples consisting of two high school graduates was $23,770 in 1981, well below the mean of $39,200 for couples with 4 or more years of college. Couples with less than high school educations earned an average of $14,820.

Husbands with 4 or more years of college accounted for 24 percent of all husbands with earnings. Men in this category averaged $27,340 for those with 4 years of college and $32,860 for men with 5 or more years of college. Thirty-seven percent of working husbands had a high school education; these men earned an average of $18,970 in 1981.

An examination of the educational attainment of working wives shows that 13.5 million, about 49 percent, had a high school education, while 17 percent completed at least 4 years of college.

The earnings of wives increases, as expected, with the level of education. Wives with high school educations earned $7,900 in 1981, while wives with 4 years of college received almost $2,800 more, averaging $10,680. The 1.9 million wives with 5 or more years of college had mean earnings of $14,910.

Figure 3A. **Years of School Completed by Husbands and Wives in Married-Couple Families With Earnings: 1981**

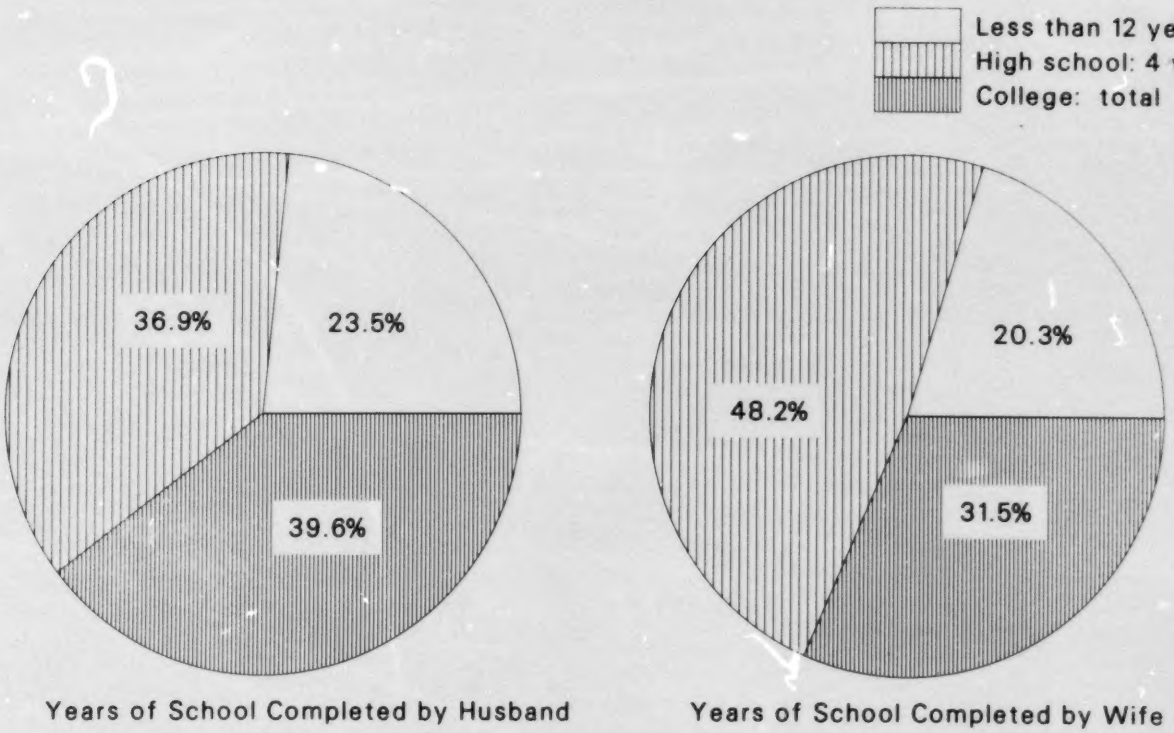


Figure 3B. **Mean Earnings of Husbands, by Years of School Completed: 1981**

Age and Presence of Children

Tables 4A through 5B contain data similar to that shown in previous sections but use the age of the husband and wife as a major classifier. Table 4A shows the earnings of married couples by age and characteristics of the husband. Tables 4C and 5B contain data on the earnings of husbands and wives by age and presence of own children.

Some of the most interesting data in this section can be found in table 5B. This table allows comparisons of the work experience and earnings levels of wives by the presence of children.

There were 27.7 million wives with earnings in 1981. Of these women, 12.5 million (about 45 percent) had no own children at home under age 18. The remaining 55 percent had one or more minor children living at home. About 3.9 million families, or 14 percent of wives with earnings, had only children under age 6; 9 percent, or 2.6 million, had both children under age 6 and children between the ages of 6 and 17. The remaining wives (31 percent) had children only between ages 6 and 17.

Over half of the women with earnings with no own minor children worked year round, full time, as compared with 31 percent for women with children only under the age of 6. Twenty-eight percent of those with children both under age 6 and 6 to 17 years worked year round, full time.[1] When all children were between the ages of 6 and 17, 44 percent of wives with earnings were employed year round, full time.

The mean earning levels of working wives varied by the presence of children: Wives with no minor children averaged $9,590, those with only children under the age of 6 had average earnings of $7,380, wives with some children under age 6 and between 6 and 17 averaged $6,580, and when all children were between the ages of 6 and 17, working wives earned an average of $8,320.

[1] There is some evidence of a difference between these estimates of 31 percent and 28 percent.

Figure 4. **Mean Earnings of Wives, by Age of Own Children Under 18 18 Years Old: 1981**

Wives With Earnings Greater Than Their Husbands

The data in table 6 show that 4.1 million wives had earnings exceeding those of their husbands in 1981. This number represents approximately 16 percent of the 25.7 million married couples in which both the husband and wife received earnings. About 8 percent of the wives in these couples had earnings ranging between 80 and 100 percent of their husbands.

Characteristics of wives earning more than their husbands differed significantly from those earning lesser amounts. Fifty-five percent of the wives earning more than their husbands had no minor children at home as compared with 40 percent for women earning less. While 17 percent of the women earning less worked in professional occupations, 25 percent of the wives with greater earnings were employed in this occupation group. Twenty-three percent of the wives that received higher pay than their employed spouses had 4 or more years of college, compared with 17 percent for wives earning less.

Husbands and Wives Both Year-Round, Full-Time Workers

The final four tables, 7A through 8B, present mean earnings figures for husbands and wives working year round, full time. Mean earnings in these tables are shown by age, occupation, and educational attainment.

As mentioned previously, 9.6 million married-couple families with earnings had both the husband and wife working year round, full time in 1981. These couples accounted for about 23 percent of all married couples with earnings in that year. The mean earnings of husbands working year round, full time whose wife also worked year round, full time was $21,490 in 1981. Mean earnings of wives working year round, full time whose husband also worked year round, full time was $13,250 in 1981. Husbands working in professional occupations earned an average of $26,680, the highest of all occupation groups shown in table 7A.

In terms of educational attainment, the data show the highest earnings levels for husbands and wives with 5 or more years of college, $29,900 and $19,440, respectively, for 1981.

Definitions and Explanations Appendix A.

Population coverage. This report includes the civilian noninstitutional population of the United States and approximately 609,000 members of the Armed Forces in the United States living off post or with their families on post, but excludes all other members of the Armed Forces.

Money wages or salary. Money wages or salary is total money earnings received for work performed as an employee during the income year. It includes wages, salary, Armed Forces pay, commissions, tips, piece-rate payments, and cash bonuses earned before deductions were made for taxes, bonds, pensions, union dues, etc.

Net income from nonfarm self-employment. Net income from nonfarm self-employment is net money income (gross receipts minus expenses) from one's own business, professional enterprise, or partnership. Gross receipts include the value of all goods sold and services rendered. Expenses include costs of goods purchased, rent, heat, light, power, depreciation charges, wages and salaries paid, business taxes (not personal income taxes), etc. In general, inventory changes were considered in determining net income; replies based on income tax returns or other official records do reflect inventory changes. However, when values of inventory changes were not reported, net income figures exclusive of inventory changes were accepted. The value of saleable merchandise consumed by the proprietors of retail stores is not included as part of net income.

Net income from farm self-employment. Net income from farm self-employment is net money income (gross receipts minus operating expenses) from the operation of a farm by a person on his own account, as an owner, renter, or sharecropper. Gross receipts include the value of all products sold, government farm programs, money received from the rental of farm equipment to others, and incidental receipts from the sale of wood, sand, gravel, etc. Operating expenses include cost of feed, fertilizer, seed, and other farming supplies, cash wages paid to farmhands, depreciation charges, cash rent, interest on farm mortgages, farm building repairs, farm taxes (not State and Federal personal income taxes), etc. The value of fuel, food, or other farm products used for family living is not included as part of net income. In general, inventory changes were considered in determining net income only when they were accounted for in replies based on income tax returns or other official records which reflect inventory changes; otherwise inventory changes were not taken into account.

Total money earnings. Total money earnings is the algebraic sum of money wages or salary and net income from farm and nonfarm self-employment.

Mean earnings. The mean earnings is the amount obtained by dividing the total earnings of a group by the number of units in that group. The means for married-couple families, husbands, and wives are based on married-couple families, husbands, and wives with earnings.

Married couple. A married couple, as defined for census purposes, is a husband and wife enumerated as members of the same household. The married couple may or may not have children living with them. The expression "husband-wife" or "married-couple" before the term "household," or "family," indicates that the household, or family, is maintained by a husband and wife.

Age. The age classification is based on the age of the person at his last birthday.

Own children under 18 years of age. "Own" children in a family are sons and daughters, including stepchildren and adopted children of the householder.

Years of school completed. Data on years of school completed were derived from the combination of answers to questions concerning the highest grade of school attended by the person and whether or not that grade was finished. The questions of educational attainment apply only to progress in "regular" schools. Such schools include graded public, private, and parochial elementary and high schools (both junior and senior), colleges, universities, and professional schools (whether day schools or night schools). Thus, regular schooling is that which may advance a person toward an elementary school certificate, a high school diploma, or a college, university, or professional school degree. Schooling in other than regular schools was counted only if the credits obtained were regarded as transferable to a school in the regular school system.

Occupation. The data on occupation refer to the civilian job held longest during the income year.

The occupation groupings were derived from occupation subgroups delineated on the basis of the classification system used in the 1970 census. For information, see Bureau of the Census Technical Paper No. 26, *1970 Occupation and Industry Classification in Terms of Their 1960 Occupation and Industry Elements,* by John A. Priebe, Joan Heinkel, and Stanley Greene, July 1972.

Work experience. A person with work experience is one who, during the preceding calendar year, did any civilian work for pay or profit or worked without pay on a family-operated farm or business at any time during the year, on a part-time or full-time basis.

Weeks worked in the income year. Persons are classified according to the number of different weeks, during the preceding calendar year, in which they did any civilian work for pay or profit (including paid vacations and sick leave) or worked without pay on a family-operated farm or business.

Part-time or full-time jobs. A person is classified as having worked at part-time jobs during the preceding calendar year if he worked at civilian jobs which provided less than 35 hours of work per week in a majority of the weeks in which he worked during the year. He is classified as having worked at full-time jobs if he worked 35 hours or more per week during a majority of the weeks in which he worked.

Year-round, full-time worker. A year-round, full-time worker is one who worked primarily at full-time civilian jobs for 50 weeks or more during the preceding calendar year.

Nonworker. A nonworker is one who did not do any civilian work in the calendar year preceding the survey.

Rounding. Percentages are rounded to the nearest tenth of a percent; therefore, the percentages in a distribution do not always add to exactly 100.0 percent. The totals, however, are always shown as 100.0. Moreover, individual figures are rounded to the nearest thousand without being adjusted to group totals, which are independently rounded; percentages are based on the unrounded numbers.

Base figures. The base figures shown for 1981 are based on civilian noninstitutional population controls for age, race, and sex established by the 1980 census.

Symbols. A dash (—) represents zero or rounds to zero, the symbol "B" means that the base for the derived figure is less than 75,000, the symbol "X" means not applicable, and the symbol "NA" means not available.

Underreporting of income. This section discusses some important aspects of underreporting and its measurement and presents some estimates of underreporting for the base year of 1979. The general survey phenomenon that is commonly termed underreporting actually refers to the tendency of household surveys to underestimate the number of income recipients and/or the amount of income received. There are three main causes for underreporting: failure to report receipt of the income type, underreporting of the amount received, and misclassification of the income type received.

Accurately measuring the extent of underreporting of income is difficult for many of the income types. There are two main components of measuring underreporting: the number of income recipients and the total amount of income received. Measuring the survey undercount of recipients for the March CPS is extremely difficult because independent estimates (benchmarks or controls) for the CPS noninstitutional, "ever-received during the year" recipient concept are difficult to validate. In addition, some of the administrative sources required for the derivation of independent estimates have significant errors themselves.

The derivation of accurate underreporting estimates for amounts of income is easier but still not without similar problems. In general, better administrative data are available on the annual amount of benefits received, or income earned, than recipients. Some of the more important problems associated with development of the independent controls for amounts are adjusting independent estimates to the CPS noninstitutional population, significant differences between alternate sources of independent estimates, especially for self-employment income, interest, dividends, and rents, and periodic revisions to the sources of independent estimates that delay availability of data and significantly alter estimates of underreporting. Shown in table A-1 are estimates of underreporting for amounts of money income for 1979.

Table A-1. Comparisons of CPS Aggregate Money Income in 1979 with Independently Derived Estimates, by Source of Income
(Billions of dollars)

Source of income	Independent estimate	CPS estimate	CPS as a percent of independent
Total	$1,740.4	$1,549.4	89.1

Source and Reliability of the Estimates

Appendix B.

SOURCE OF DATA

The estimates are based on data obtained in March 1982 from the Current Population Survey (CPS) of the Bureau of the Census and from supplementary questions to the CPS. The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and over in every sample household. In addition, supplementary questions are asked every March about money income and work experience for the previous year. In order to obtain more reliable data for the Spanish-origin population, the March CPS sample was enlarged to include all households from the previous November sample which contained at least one sample person of Spanish origin. For this report, persons in the Armed Forces living off post or with their families on post are also included.

The present CPS sample was initially selected from the 1970 census files with coverage in all 50 States and the District of Columbia. The sample is continually updated to reflect new construction. The current CPS sample is located in 629 areas comprising 1,148 counties, independent cities, and minor civil divisions in the Nation. In this sample, approximately 61,500 occupied households were eligible for interview. Of this number, about 2,500 occupied units were visited but interviews were not obtained because the occupants were not found at home after repeated calls or were unavailable for some other reason.

The estimation procedure used in this survey involved the inflation of the weighted sample results to independent estimates of the total civilian noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from decennial censuses; statistics on births, deaths, immigration and emigration; and statistics on the strength of the Armed Forces. The estimation procedure for the data in the report also involved a further adjustment so that husband and wife of a household received the same weight. The independent population estimates used in this report are based on the 1980 decennial census.

RELIABILITY OF ESTIMATES

Since the CPS estimates are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaire, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey: sampling and nonsampling. The standard errors provided for this report primarily indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of the respondents to provide correct information, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, and failure to represent all units with the sample (undercoverage).

Undercoverage in the CPS results from missed housing units and missed persons within sample households. Overall CPS undercoverage, as compared with the level of the 1980 decennial census, is about 7 percent. It is known that CPS undercoverage varies with age, sex, and race. Generally, undercoverage is larger for males than for females and larger for Blacks and other races combined than for Whites. Ratio estimation to independent age-sex-race population controls partially corrects for the bias due to survey undercoverage. However, biases exist in the estimates to the extent that missed persons in missed households or missed persons in interviewed households have different characteristics than interviewed persons in the same age-sex-race group. Further, the independent population controls used have not been adjusted for undercoverage in the decennial census.

A coverage improvement sample was included in computing the estimates in order to provide coverage of mobile homes and new construction housing units which previously had no chance for selection under the CPS design. This sample is composed of approximately 450 sample household units which represent 237,000 occupied mobile homes and 600,000 new construction housing units. These new construction units are composed of those units where building permits were issued prior to January 1970 and construction was not completed by the time of the 1970 census (i.e., April 1970). The extent of other sources of housing undercoverage is unknown but believed to be small. The inclusion of this coverage improvement sample in the CPS does not have a significant effect on the estimates.

In most cases the questionnaire entries for income are based on the memory or knowledge of one person, usually

the wife. The memory factor in data derived from field surveys of income probably produces underestimates because the tendency is to forget minor or irregular sources of income. Other errors of reporting are due to misrepresentation or to misunderstanding as to the scope of the income concept. See also the section entitled "Underreporting of Income."

Sampling variability. The standard errors given in tables B-1 through B-6 are primarily measures of sampling variability, that is, of the variation that occurred by chance because a sample rather than the entire population was surveyed. The sample estimate and its standard error enable one to construct confidence intervals, ranges that would include the average result of all possible samples with a known probability. For example, if all possible samples were selected, each of these being surveyed under essentially the same general conditions and using the same sample design, and if an estimate and its standard error were calculated from each sample, then:

1. Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average result of all possible samples.
2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.
3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses appearing in this report are 1) the population parameters are identical or 2) they are different. An example of this would be comparing the mean earnings of married-couple families where the wife worked versus the mean earnings of married-couple families where the wife did not work. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical. All statements of comparison in the text have passed a hypothesis test at the 0.10 level of significance or better, and most have passed a hypothesis test at the 0.05 level of significance or better. This means that, for most differences cited in the text, the estimated difference between parameters is greater than twice the standard error of the difference. For the other differences mentioned, the estimated difference between parameters is between 1.6 and 2.0 times the standard error of the difference. When this is the case, the statement of comparison will be qualified in some way, e.g., by use of the phrase "some evidence."

Note when using small estimates. Summary measures (such as means, medians, and percent distributions) are shown only when the base is 75,000 or greater. Because of the large standard errors involved, there is little chance that summary measures would reveal useful information when computed on a smaller base. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for the corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's needs.

Standard error tables and their use. In order to derive standard errors that would be applicable to a large number of estimates and that could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error.

The figures presented in tables B-1 and B-2 are approximations to standard errors of various estimates for married-couple families, husbands and wives in the United States. Estimated standard errors for intermediate values not shown in the generalized tables of standard errors may be approximated by linear interpolation.

Two parameters (denoted "a" and "b") are used to calculate standard errors for each type of characteristic; they are

Table B-1. Standard Errors of Estimated Numbers
(Numbers in thousands)

Size of estimate	Standard error
25	7
75	11
100	13
250	21
500	29
1,000	41
2,000	58

30,000	0.11	0.2	0.2	0.3	0.4
40,000	0.09	0.14	0.2	0.3	0.3
50,000	0.08	0.13	0.2	0.3	0.3

also presented in table B-3. These parameters were used to calculate the standard errors in tables B-1 and B-2. They also may be used to directly calculate the standard errors for estimated numbers and percentages. Methods for direct computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error, σ_x, of an estimated number can be obtained in two ways. It may be obtained by interpolation from table B-1. Alternatively, standard errors may be approximated by using formula (1), from which the standard errors were calculated in table B-1. Use of this formula will provide more accurate results than the use of table B-1.

$$\sigma_x = \sqrt{ax^2 + bx} \qquad (1)$$

Here x is the size of the estimate and a and b are the parameters in table B-3 associated with the particular type of characteristic.

Table B-3. "a" and "b" Parameters for Calculating Approximate Standard Errors of Estimated Numbers and Percentages

Characteristic	Parameter	
	a	b
All characteristics.....	-0.000010	1,721

Note: These are the parameters to be used in formulas (1) and (2).

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depend upon both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. The approximate standard error, $\sigma_{(x,p)}$, of an estimated percentage can be obtained from table B-2. Alternatively, standard errors may be approximated by using formula (2), from which the standard errors in table B-2 were calculated. Use of this formula will provide more accurate results than use of table B-2.

$$\sigma_{(x,p)} = \sqrt{\frac{b}{x} \cdot p(100-p)} \qquad (2)$$

Here x is the size of the subclass of families, husbands, or wives which is the base of the percentage, p is the percentage ($0<p<100$), and b is the parameter in table B-3 associated with the particular type of characteristic in the numerator of the percentage.

Illustration of the use of standard error tables. Table 1A of this report shows that in 1981 there were 42,199,000 married-couple families with earnings. Table B-3 indicates that the appropriate "a" and "b" parameters to use in calculating a standard error for this estimate are a = -0.000010 and b = 1,721. Using formula (2), the approximate standard error is

$$\sqrt{(-0.000010)\,(42{,}199{,}000)^2 + 1{,}721\,(42{,}199{,}000)} = 234{,}000^1$$

The 68-percent confidence interval as shown by the data is from 41,965,000 to 42,433,000. The 95-percent confi-

[1] Interpolation from table B-1 also gives a standard error of 234,000.

Table B-4. Number, Mean Earnings, and Standard Errors of Mean Earnings Amount, by Selected Characteristics of Married Couples: 1981

(Married-couple families as of March 1982)

Characteristic	Number with earnings (thousands)	Mean earnings	
		Value (dollars)	Standard error (dollars)
Total	42,199	25,551	109
Both husband and wife worked, total	26,258	28,562	131
Both husband and wife worked year round, full time	9,627	34,555	212
Husband worked, wife did not	13,991	22,301	193
Husband a craft worker, wife a clerical worker	2,128	27,795	328
Both husband and wife a professional or managerial worker	3,742	39,173	423
Both husband and wife with 4 years of high school	10,556	23,773	163
Both husband and wife with 4 or more years of college	4,594	39,200	422
Both husband and wife with less than 4 years of high school	5,456	14,815	190

dence interval is from 41,731,000 to 42,667,000 (using twice the standard error). Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 95 percent of all possible samples.

Table 1A also shows that in 66.8 percent of the 42,199,000 married-couple families with earnings, the wife worked in 1981. Using formula (2) and the appropriate b parameter of 1,721 from table B-3, the standard error of 66.8 percent is given by

$$\sqrt{\frac{1{,}721}{42{,}199{,}000}\ 66.8(100.0-66.8)} = 0.3^2$$

Thus, the 68-percent confidence interval on the estimated percentage is from 66.5 to 67.1, and the 95-percent confidence interval is from 66.2 to 67.4.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\sigma_x^2 + \sigma_y^2} \qquad (3)$$

where σ_x and σ_y are the standard errors of the estimates x and y. The estimates can be of numbers, percents, ratios, etc.

Illustration of the computation of the standard error of a difference. Table 1A shows that of married-couple families with earnings, 44.4 percent had wives working full time and 22.4 percent had wives working part time. Using formula (2), the standard errors on both these estimates is 0.3 percent. Therefore, the standard error of the estimated difference of 22.0 percent is

$$\sqrt{(0.3)^2 + (0.3)^2} = 0.4 \text{ percent}$$

This means that the 68-percent confidence interval on the difference of 22.0 percent as shown by these data is from 21.6 to 22.4. The 95-percent confidence interval on the difference of 22.0 is from 21.2 to 22.8. Therefore, a conclusion that the average estimate of the difference derived from all possible samples lies within a range computed in this way would be correct for roughly 95 percent of all possible samples. Since this interval does not contain zero, we can conclude with 95-percent confidence that a higher percentage of wives worked full time than part time in married-couple families with earnings.

Standard errors of estimated mean earnings. Tables B-4, B-5, and B-6 provide standard errors of estimated mean earnings for some of the estimates in this report. However, because of the approximations used in developing the formula used to estimate the standard error of a mean, the standard error reported for this statistic will generally be an underestimate. Standard errors for estimates not provided in tables B-4, B-5, and B-6 can be obtained by contacting Population Division of the Census Bureau.

Standard error of a ratio of means. Certain tables in this report contain ratios of wives' earnings to husbands' earnings. Standard errors for these ratios may be approximated by the following formula:

$$\sigma_{\left(\frac{x}{y}\right)} = \sqrt{\left(\frac{x}{y}\right)^2 \left[\left(\frac{\sigma_y}{y}\right)^2 + \left(\frac{\sigma_x}{x}\right)^2\right]} \qquad (4)$$

Here, $\frac{x}{y}$ is the ratio of the wives earnings to the husbands earnings. The standard error of the estimated mean earnings for wives, σ_x, and the standard error of the estimated mean earnings for husbands, σ_y, not provided in tables B-4, B-5, and B-6 can be obtained by contacting Population Division of the Census Bureau.

[2] Interpolation from table B-2 also gives a standard error of 0.3.

Table B-5. Number, Mean Earnings, and Standard Error of Mean Earnings Amount, by Selected Characteristics of Husbands: 1981

(Husbands as of March 1982)

Characteristic	Number with earnings (thousands)	Mean earnings	
		Value (dollars)	Standard error (dollars)
Total	40,245	20,866	99
Worked year round, full time	30,774	23,800	114
Worked year round, fuil time, wife did not work	10,334	26,166	225
Worked in craft occupations	9,340	18,723	132
Worked in professional occupations	6,881	28,225	288
Worked in managerial occupations	6,919	27,778	311
With 4 years of college	5,002	27,343	323
With 5 or more years of college	4,611	32,863	431
With 4 years of high school	15,017	18,967	126
Worked year round, full time, wife worked year round, full time	9,626	21,492	171
Worked year round, full time in professional occupations, wife worked year round, full time	1,905	26,676	430
With 5 or more years of college, worked year round, full time, wife worked year round, full time	1,197	29,901	661

Table B-6. Number, Mean Earnings, and Standard Error of Mean Earnings Amount, by Selected Characteristics of Wives: 1981

(Wives as of March 1982)

Characteristic	Number with earnings (thousands)	Mean earnings	
		Value (dollars)	Standard error (dollars)
Total	27,698	8,598	56
Worked year round, full time	12,654	13,067	79
Worked part time	9,168	3,831	54
Worked in clerical occupations	9,453	8,903	80
Worked in professional or managerial occupations	7,140	12,196	140
With 4 years of high school	13,459	7,897	70
With 4 years of college	2,966	10,681	195
With 5 or more years of college	1,851	14,914	329
With no minor children	12,498	9,594	86
With children under 6 years of age, none older	3,854	7,379	142
With children under 6 years and children 6 to 17 years	2,623	6,575	172
With children 6 to 17 years, none younger	8,723	8,318	97
Worked year round, full time, husband worked year round, full time	9,494	13,250	93
With 5 or more years of college, worked year round, full time, husband worked year round, full time	867	19,444	399
